37% of new players come back the next day, 3% two weeks later

Total players	D1 retention	D7 retention	Ad revenue
71 679	37.0%	6.7%	$38,417

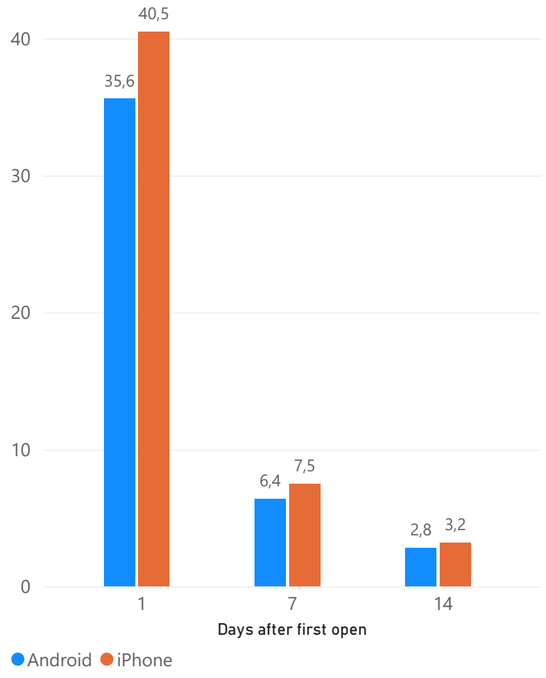

Daily active players (27 Mar: data gap, cause not established)

New-player funnel (% of players; purchase tracked on Android only)

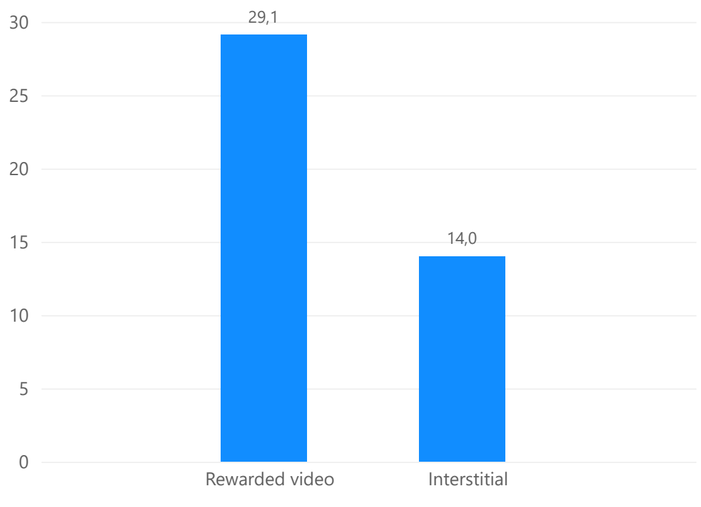

Retention by platform (% of new players, D1 / D7 / D14)

Notes: Purchases are tracked on Android only, so the last funnel step is understated. 28 Feb and 10 Apr are partial days. At D14 the platform confidence intervals overlap: no conclusion. Ad revenue is an ad-network estimate. Source: Kaggle Player Analytics Event Stream Data (CC BY 4.0), 71M events. Retention = new players (firstOpen), fully observed cohorts only.

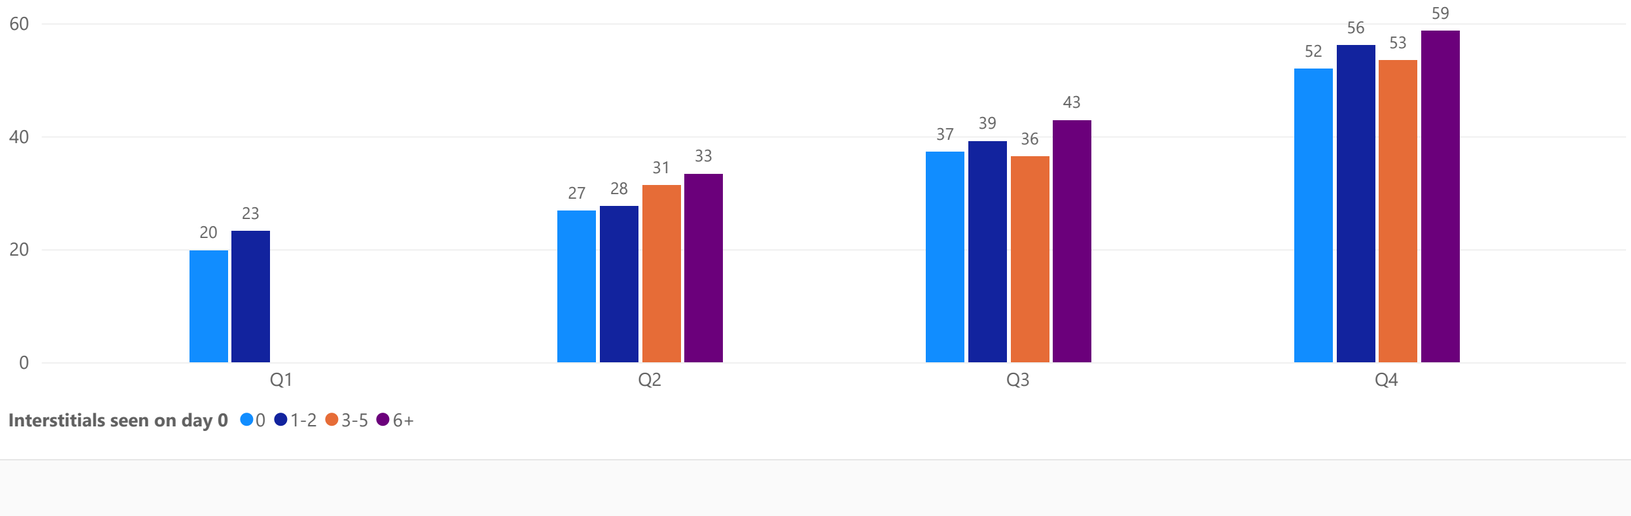

Rewarded video pays 2x more than interstitials; no sign that ads push new players away

eCPM by ad format (USD per 1,000 impressions, network estimate)

At the same activity level, new players who see more interstitials on day 0 do not come back less

D1 retention (%) by interstitials seen on day 0, within quartiles of day-0 activity. Observational: ads follow play time, so this is not proof either way. Cells under 100 players hidden.

AdsConfig_iOS test: no D1 difference detected between variants

Variant	Players	Interstitials on day 0 (mean)	D1 retention (%)
Control-Variant	1022	7,52	38,30
Variant-A	1011	7,94	38,30
Variant-B	1028	6,05	39,70

Notes: ad revenue and eCPM are ad-network estimates. Activity quartiles split new players by the number of gameplay events on day 0 (Q1 = least active). Cells with fewer than 100 players are hidden. AdsConfig_iOS: with about 1,000 players per variant, only a D1 change of about 6 points could be detected; a 2-point change needs about 9,400 players per variant. Variant B shows about 20% fewer interstitials on day 0 with no visible D1 loss: a lead to confirm at scale.
